Interview Performance Report

Generated On: 02-06-2026 10:25

Interview Type: Mock Interview

Topic: database

Questions Attempted: 3

Overall Performance

Average Score: 5.5/10

Recommendation: Needs Improvement

Highest Score: 7.0/10

Lowest Score: 4.0/10

Best Performance: Question 1

Needs Most Improvement: Question 2

Question-wise Evaluation

Question 1

Score: 7.0/10

Communication Score: 8/10

Technical Score: 5/10

Confidence Score: 9/10

Strengths:

- The candidate provides a clear, concise, and professional opening statement that effectively frames the architectural importance of the database choice.
- They accurately identify data modeling and schema flexibility as the core difference between SQL and NoSQL databases.
- The answer correctly lists various types of NoSQL data models (documents, key-value pairs, wide-columns, graphs), demonstrating good foundational knowledge.

Weaknesses:

- The answer is significantly incomplete, as it only addresses the first part of the question (describing differences) and entirely omits the discussion of factors for choosing a database.
- While it touches upon data modeling, it doesn't elaborate on other crucial technical differences like ACID vs. BASE properties, support for joins/referential integrity, normalization, or typical query languages.

Improvement:

- Ensure the answer fully addresses all components of the question. Specifically, dedicate time to discussing the factors that would influence the choice, such as scalability requirements, data consistency needs, schema flexibility, data volume, query patterns, and operational considerations.
- Expand the description of key differences to include fundamental concepts like transaction models (ACID for SQL, often BASE for NoSQL), query capabilities, and scaling strategies (vertical for SQL,

often horizontal for NoSQL).

Overall Score: 7/10

Question 2

Score: 4.0/10

Communication Score: 5/10

Technical Score: 6/10

Confidence Score: 8/10

Strengths:

- Provides a clear, concise, and accurate definition of database normalization.
- Correctly identifies the primary goals of normalization: minimizing data redundancy and protecting data integrity.
- Effectively uses appropriate technical terms like primary and foreign keys in the explanation.

Weaknesses:

- **Critically, the candidate failed to address two out of the three parts of the question:** "Why is it important?" and "Describe a scenario where you might intentionally choose to denormalize your database?" This is a significant oversight for any candidate, especially for a senior role.
- While the explanation of the concept is good, it lacks the depth of discussing normalization forms (1NF, 2NF, 3NF, BCNF) which is often expected when explaining the concept to a senior interviewer.

Improvement:

- **Ensure all parts of a multi-part question are addressed.** A good strategy is to mentally (or physically, if allowed) break down the question into its components before answering.
- Elaborate on the *importance* of normalization, discussing benefits such as data consistency, easier data maintenance, improved update efficiency, and reduced storage space.
- Provide a detailed scenario for intentional denormalization, explaining the specific trade-offs (e.g., improved read performance for reporting/analytical queries at the cost of increased data redundancy and potential update anomalies).

Overall Score: 4/10
